PrintTo("dataParams",Params);

```

2 Short description

First we import the necessary `GAP3` packages, define the variables and define the Hecke algebra we need. In this example we define the Hecke algebra of G_5 at variables a , b , c and d . Note that originally the algebra has seven variables. But by dividing each relation satisfied by the generators by one of the variables of this relation, we can reduce the number of variables by one for every relation. This makes the calculations less computationally intensive. This corresponds to the relations $(s-1)(s-a)(s-b) = 0$ and $(t-1)(t-c)(t-d) = 0$ of the algebra, where s and t are the generators. Moreover, we extract the data necessary for the computation.

```

RequirePackage("chevie");
RequirePackage("vkcurve");

W:=ComplexReflectionGroup(5);
a:=Mvp("a");
b:=Mvp("b");
c:=Mvp("c");
d:=Mvp("d");
H:=Hecke(W,[[1,a^6,b^6],[1,c^6,d^6]]);

R:=Representations(H);
L:=Length(R);
S:=SchurElements(H);

CharIrr := CharTable(W).irreducibles;
Hyp := HyperplaneOrbits(W);
Params := H.parameter;

```

The function `F` corresponds to the first condition (trace). Since the computations in `GAP3` take a long time to be completed, this function has been reimplemented in `Mathematica`.

```

F:=function(g) local res,i,l,R,L,S;
  R:=Representations(H);
  L:=Length(R);
  S:=SchurElements(H);
  if g=[] then res:=Sum(List([1..L],1->Length(R[l][1])/S[l]));
  else res:=Sum(List([1..L],1->Trace(Product(List(g,
      i->R[l][AbsInt(i)]^(SignInt(i)))))/S[l]));
  fi;
return res;
end;

```

The next functions are helper functions for the computations related to the third condition.

```

m:=function(W,i,s)local char,s,classnos,o;
    char:=CharTable(W).irreducibles[i];
    s:=HyperplaneOrbits(W)[s];
    classnos:=Concatenation([1],s.classno);
    o:=s.e_s;
    return List([0..o-1],j->Sum([0..o-1],
        k->char[classnos[k+1]]*E(o)^(-k*j))/o);
end;

omegapi:=function(W,H,i) local d,j,s,t,C,r,o,M,res;
    d:=CharTable(W).irreducibles[i][1];
    res:=1;
    for j in HyperplaneOrbits(W) do
        s:=j.s;
        t:=H.parameter[s];
        C:=HyperplaneOrbits(W)[s];
        o:=C.e_s;
        M:=m(W,i,s);
        res:=res*Product(List([1..o],
            k->((E(o)^(-k+1)*t[k])^(M[k]*C.N_s*C.e_s*d^-1))));
    od;
return res;
end;

```

Now, we define the function G that corresponds to the third condition. Again, this function (as well as the helper functions) has been reimplemented in Mathematica.

```

G:=function(g) local res,i,l,ginv,R,L,S;
    R:=Representations(H);
    L:=Length(R);
    S:=SchurElements(H);
    if g=[] then
        res:=Sum(List([1..L],l->(omegapi(W,H,l)*Length(R[l][1]))/S[l]));
    else
        ginv:=(-1)*Reversed(g);
        res:=Sum(List([1..L],l->(omegapi(W,H,l)*Trace(Product(List(ginv,i->R[l]
            [AbsInt(i)]^(SignInt(i)))))/S[l]));
    fi;
return res;
end;

```

Moreover, we define the basis of the algebra, where 1 corresponds to the generator s and 2 to the generator t . Finally, we output the data of GAP3 to text files, which are later imported into Mathematica.

```
